CAPROV

AI-FIRST PRIVATE-ASSET INTELLIGENCE

Business & Product Profile

A trusted operating layer for information-rich, complex private assets.

PREPARED AS A CONCISE BUSINESS BRIEF · OCTOBER 2026

> **CAPROV converts fragmented private-asset information into structured, traceable intelligence and connects it to the workflows used to manage, finance and transact on those assets.**

1 Startup Overview

WITHIN 300 WORDS

CAPROV is an AI-first private-asset intelligence platform designed for organizations that need a clearer, defensible view of assets whose information is scattered across documents, systems and stakeholders. It brings document intake, structured extraction, valuation evidence, risk analysis, portfolio visibility and capital-markets workflows into a single operator environment.

At the center of the product is **Asset DNA**: a versioned digital representation of an asset built from source documents and maintained with provenance. CAPROV classifies uploaded files, extracts normalized facts, links them to supporting fragments and uses the resulting intelligence layer to produce valuation marks, risk views, projections and analyst-ready briefings. The product is designed for private-market contexts where trust in the underlying information matters as much as speed.

CAPROV is delivered as a modular platform: a responsive web console, a NestJS business API and a deterministic Python intelligence engine. Around the intelligence core, the platform supports asset management, document operations, portfolio monitoring, marketplace listings, trading, settlement, collateral and lending. Tokenization and provenance anchoring capabilities are available through Ethereum Sepolia integrations, with simulated operation supported for end-to-end workflow testing.

2 Founder & Team Profile

WITHIN 150 WORDS

CAPROV is being developed by a cross-functional product and engineering team focused on the intersection of private assets, data trust and applied AI. The team’s approach combines enterprise application design with document intelligence, capital-markets workflow modeling and blockchain-enabled provenance.

The operating model reflected in the product spans full-stack web engineering, API and domain-platform development, deterministic AI and extraction engineering, and security-conscious workflow design. This

multidisciplinary structure is important because CAPROV must connect highly practical activities—document review, approvals and portfolio operations—with explainable analytics and transaction-ready records.

Founder names and individual biographies were not included in the technical product materials available for this brief. The profile should therefore be supplemented with the approved founder credentials, domain experience, ownership structure and advisory relationships before external circulation.

3 Problem Statement

WITHIN 150 WORDS

Private assets often lack a common, current and auditable source of truth. Critical evidence is distributed across valuation packs, title or ownership documents, financial statements, inspection reports, contracts and emails. Analysts must manually reconcile inconsistent facts, while investment, risk, compliance and operations teams work from different versions of the same asset story.

This creates slower diligence, fragile valuations, limited portfolio transparency and avoidable operational risk. It also makes downstream workflows—such as collateral assessment, marketplace listing, settlement or lending—harder to govern because the rationale behind an asset mark is not consistently connected to its source evidence.

CAPROV addresses this gap by creating a structured evidence layer that can be reviewed by people, consumed by systems and carried through the asset lifecycle.

4 Product Details & Key Differentiator

WITHIN 150 WORDS

Document to Asset DNA

Classifies files and extracts normalized facts with document and fragment provenance.

Intelligence for decisions

Produces versioned valuation, risk and projection views alongside an analyst copilot.

Workflow continuity

Connects assets to portfolios, trading, settlement, collateral, lending and tokenization modules.

Governed by design

Provides RBAC, organization controls, audit trails and content-hashed intelligence snapshots.

The key differentiator is CAPROV’s evidence-first design. Asset DNA is not simply a narrative summary: it is a versioned, provenance-aware data envelope that retains links to source facts. CAPROV keeps the core extraction and marking path deterministic, while allowing organizations to select LLMs for copilot assistance where appropriate. This separation helps preserve explainability and control in workflows where unsupported AI output is unacceptable.

5 Early Validation & Use Case Deployment

WITHIN 150 WORDS

CAPROV has a functional integrated product build covering the full path from document upload to Asset DNA, valuation and risk views, and downstream capital-markets workflows. The local demonstration environment includes seeded assets and documents, role-based user journeys, a responsive analyst console, API documentation and an independent intelligence-engine health service.

Demonstrable use cases include: reviewing a valuation or ownership pack; creating and versioning Asset DNA; tracing a valuation mark to supporting evidence; generating a risk or forward-projection view; managing a portfolio; and progressing an asset through listings, trading, settlement, collateral or lending workflows. Provenance anchors and tokenization flows can be exercised in simulated Sepolia mode, enabling workflow validation without requiring live-chain credentials.

These capabilities establish technical and workflow readiness; external customer traction, pilot outcomes and commercial metrics should be added once approved for disclosure.

6 Any Other Information

WITHIN 150 WORDS

CAPROV has been designed for controlled enterprise adoption. Organizations can manage users and role-based access, select an approved copilot model, maintain audit records and operate within a tenant-aware environment. The system also supports resilient deployment: when the Python intelligence service is unavailable, the API can fall back to equivalent local deterministic extraction logic; when remote model credentials are absent, copilot can fall back to deterministic retrieval.

The platform is intentionally modular, allowing an organization to begin with document intelligence and Asset DNA, then expand into portfolio operations and capital-markets capabilities as governance and business requirements mature. This provides a practical route to adoption without requiring a wholesale replacement of existing systems on day one.

Disclosure note: This brief is based on the current CAPROV product repository and documentation. It describes product capabilities and demonstration readiness; it does not assert customer deployments, revenue, regulatory approval or live-chain production activity.
